A 171 812 bp nucleotide sequence between *prkA* and *addAB* (83° to 97°) on the genetic map of the *Bacillus subtilis* 168 chromosome was determined and analysed. An accurate physical/genetic map of this previously poorly described chromosomal region was constructed. One hundred and seventy open reading frames (ORFs) were identified on this DNA fragment. These include the previously described genes *cspB*, *glpPFD*, *spoVR*, *phoAIV*, *papQ*, *citRA*, *sspB*, *prxA*, *hpr*, *pbpF*, *hemEHY*, *aprE*, *comK* and *addAB*. ORF *yhaF* in this region corresponds to the *glyB* marker. Among the striking features of this region are: an abundance of genes encoding (putative) transporter proteins, several dysfunctional genes, the ubiquitous *hit* gene, and five multidrug-resistance-like genes. These analyses have also revealed the existence of numerous paralogues of ORFs in this region: about two-thirds of the putative genes seem to have at least one paralogue in the *B. subtilis* genome.

Keywords: genome sequencing, functional genomics, paralogous genes, *Bacillus subtilis*

INTRODUCTION

Since 1995, when the Gram-negative bacterium *Haemophilus influenzae* was the first free-living organism to be entirely determined at the DNA level (Fleischmann *et al.*, 1995), the sequences of several other microbial genomes have been elucidated. Among these are the smallest known genome of the bacterium *Mycoplasma genitalium* (Fraser *et al.*, 1995), and the genomes of the archaeon *Methanococcus jannaschii* (Bult *et al.*, 1996), the bacterium *Mycoplasma pneumoniae* (Himmelreich *et al.*, 1996), the bacterium *Escherichia coli* (O'Brien, 1997), the cyanobacterium *Synechocystis* PCC 6803 (Kaneko *et al.*, 1996) and the eukaryote *Saccharomyces cerevisiae* (Goffeau *et al.*, 1996; Mewes *et al.*, 1997). In the framework of the combined European/Japanese

Bacillus subtilis genome sequencing project that was recently completed (Kunst *et al.*, 1997), a 171 812 bp DNA sequence, representing 4.1% of the genome, was determined and analysed by our group. The sequence spans the region between 83° (*prkA*) and 97° (*addAB*) on the genetic map of the *B. subtilis* chromosome (Anagnostopoulos *et al.*, 1993; Baudet *et al.*, 1996). The present paper deals with the cloning, sequencing and *in silico* analysis of putative genes in this region. The availability of the entire *B. subtilis* genome sequence enabled us to compare ORFs in the region analysed here with all coding sequences in the genome. These analyses revealed a high frequency of paralogous genes, i.e. genes specifying related (putative) proteins. A correction of the existing genetic (Anagnostopoulos *et al.*, 1993; Baudet *et al.*, 1996) and physical maps (Itaya & Tanaka, 1991) is also presented.

The sequence of part of this region (22 kb) has been published previously (Noback *et al.*, 1996), but for completeness this fragment has been included in this paper.

Abbreviations: LR PCR, long-range PCR; iLR PCR, inverse long-range PCR. The EMBL accession numbers for the sequences reported in this paper are X96983 and Y14077 to Y14084 inclusive.

METHODS

Bacterial strains and DNA handling procedures. *B. subtilis* 168 (*trpC2*) was used as the standard strain for sequence determinations. DNA fragments for sequencing were obtained mainly by long-range PCR (LR PCR; Cheng *et al.*, 1994; Barnes, 1994), or inverse long-range PCR (i-LR PCR) techniques, using the Gene Amp XL-PCR kit with rTth polymerase (Perkin Elmer). All amplification reactions were performed according to the protocols supplied by the manufacturer. i-LR PCR was performed by digestion of *B. subtilis* chromosomal DNA with appropriate restriction enzymes, followed by purification of the digested DNA, and subsequent self-ligation at low concentrations of DNA (<5 µg ml⁻¹). PCR primers used are listed in Table 1. An overview of the amplified fragments is presented in Fig. 1.

Some fragments were cloned as phage lambda DNA inserts. The *B. subtilis* lambda EMBL12 library, constructed from a sized partial *Sau3A* digest of the chromosome (kindly provided by Dr C. Harwood, University of Newcastle upon Tyne, UK), was screened by the plaque hybridization method (Sambrook *et al.*, 1989) for the presence of desired sequences. For sequence determinations, phage lambda DNA inserts were amplified by LR PCR and subsequently processed in the same way as other LR PCR fragments (see below).

PCR fragments used for sequencing were treated in one of the following ways.

(i) Shotgun cloning in M13mp18 phage by nebulization, followed by DNA sequencing. This method has been described in a previous paper (Noback *et al.*, 1996).

(ii) Shotgun cloning in pUC18 after limited DNase I digestion in buffer consisting of 500 mM Tris/HCl pH 7.6, 100 mM MnCl₂, 1 mg BSA ml⁻¹. Subsequently, the DNA fragments were treated with T4 DNA polymerase and Klenow enzyme (in 10 mM Tris/HCl, pH 8.5, 0.25 mM dNTPs, 5 mM MgCl₂) and fractionated by agarose gel electrophoresis. Fragments ranging from 500 to 1500 bp were extracted and ligated into pUC18 which had been digested with *Sma*I and treated with alkaline phosphatase. The ligation mixtures were used to transform *E. coli* XL-1 Blue (*supE*⁺ *lac* *hsdR17* *recA1* [*F'* *proAB*⁺ *lacI*^a *lacZ*ΔM15]) (Stratagene). DNA inserts were sequenced by the method described below.

(iii) Sequencing directly on PCR-generated DNA. To prevent sequencing mistakes that were generated during the PCR reaction, eight separate amplification reactions were performed and they were pooled.

Sequence determination. DNAs were isolated on a Vistra DNA Labstation 625 (Amersham) using either the 'automated M13 template preparation kit' or the 'automated plasmid preparation kit'. DNA inserts were sequenced by the dideoxy chain-termination method (Sanger *et al.*, 1977) using the

* A capital C means that the primer is on the complementary strand.

† In this column the second primer used for the amplification is indicated. In the case of i-LR PCR, the restriction enzyme that was used for digestion of the chromosome is also specified. 'On λ' means that the insert of a recombinant lambda phage was amplified.

Amersham 'automated Delta Taq cycle sequencing kit' and the Amersham Vistra automated DNA sequencer 725. The universal forward sequencing primer was used (5'-GTAAAA-CGACGGCCAGT-3'). Remaining gaps between the contiguous sequences obtained through shotgun cloning were determined by primer walking on PCR material using the Amersham 'sequenase PCR product sequencing kit' and [³⁵S]dATPαS.

Data handling and computer analysis. DNA sequences were assembled using the Staden package (Dear & Staden, 1991; obtained from MRC, Cambridge, UK). A redundancy of four readings per base, with a minimum of one reading for each strand, was taken as a standard for a reliable sequence. The compiled sequence was analysed for the presence of ORFs consisting of more than 50 codons using the Staden package. The amino acid sequences of the putative protein products encoded by the ORFs were analysed for similarities to known sequences in databases using the FASTA program (Pearson & Lipman, 1988), and the BLAST e-mail server at the NCBI (retrieve@ncbi.nlm.nih.gov).

Transformation and competence. *B. subtilis* cells were made competent essentially as described by Bron & Venema (1972). *E. coli* cells were made competent and transformed by the method of Mandel & Higa (1970).

Isolation of DNA. *B. subtilis* chromosomal DNA was purified as described by Bron (1990). Plasmid DNA was isolated by the alkaline-lysis method of Ish-Horowicz & Burke (1981).

RESULTS AND DISCUSSION

Cloning of the *prkA*–*addAB* region

For the cloning of the *prkA*–*addAB* region we started from two marker regions on the genetic map: the *glpPFD* operon, which was already cloned and sequenced (Beijer *et al.*, 1993; Holmberg *et al.*, 1990), and the *glyB* marker, which was only genetically mapped (Harford *et al.*, 1976). The cloning and analysis of the *yhcA*–*glpP* region (22 kb), which is part of the *prkA*–*addAB* region, has been reported in a previous paper (Noback *et al.*, 1996).

An overview of cloned fragments from this region, and the method by which they were obtained, is shown in Fig. 1. Fragments indicated in this figure as 'formerly known' were partially (at least 10%) resequenced. Other previously known sequences (*cspB*, *sspB*, *prsA*, *hpr*, *hemEHY*, *aprE* and *comK*) were resequenced in their entirety. In a total of about 15 kb of resequenced DNA, less than ten discrepancies were found, and these were present in non-coding areas.

By i-LR PCR, using *EcoRI* from *yhcA* outward in the direction of *prkA* (Fischer *et al.*, 1996), a 5 kb fragment was amplified which spans the region from *yzdC* to *yhcA*. In the other direction, from *glpD* outward in the direction of *addAB*, an i-LR PCR fragment of 7 kb was obtained using *SspI* and primers XLP21 and XLP1B. Using a terminal part of this fragment as probe, a lambda DNA clone was isolated containing an additional 3 kb. This fragment unexpectedly proved to contain part of the *spoVR*–*citA* contig (Beall & Moran,

1994; Hulett *et al.*, 1991; Jin & Sonenshein, 1994a, b), already present in *SubtiList* (the project's central database for *B. subtilis* sequences: Moszer *et al.*, 1995), and mapped outside our region.

A 13.5 kb clone was isolated by screening a lambda-GEM11 genome bank with a 4.5 kb *glyB*⁺ *SacI* chromosomal fragment (kindly provided by M. Sarvas, Helsinki, Finland). Southern analysis revealed that this clone also contained the *hpr* (Perego & Hoch, 1988) and *prsA* (Kontinen *et al.*, 1991) genes. By plasmid rescue, 'walking' in the direction of *prkA*, two *E. coli* plasmid clones were isolated containing *yhaO*–*yhaM* (5 kb) and *yhaR*–*yhaP* (4 kb), respectively. Using the divergent primers XLP17 and XLP18, and *PstI*-digested chromosomal DNA, a 12 kb DNA fragment was amplified by i-LR PCR (*yhaR* to *yheD*). Using the *yheD* end of this fragment as a probe, a clone was isolated from a lambda-GEM11 genomic bank that contained the *yheD*–*yheM* region (9 kb). Using a primer from the end of this clone, XLP402, we were able to amplify the region between *yheM* and *citA* (primer XLP401) by LR PCR, yielding a fragment of 21 kb.

Finally, three LR PCR fragments were obtained which together span the region between *glyB* and *addAB*. First, a 26 kb fragment between *yhaA* and *aprE* (Stahl & Ferrari, 1984) was amplified using primers XLP36 and XLP06. Unexpectedly, this fragment contained the *hemEHY* gene cluster (Hansson & Hederstedt, 1992) that was formerly mapped at a different position (94°). Second, a 12.5 kb fragment was generated between *aprE* and *comK* (primers XLP07 and XLP05). Finally, a PCR fragment was obtained between *comK* and *addB* (primers XLP04 and XLP08), yielding a fragment of 18 kb.

Updating and correction of the genetic map of the *prkA*–*addAB* region

From our cloning and sequencing data, it became clear that the genetic map of this region (Anagnostopoulos *et al.*, 1993) contained several errors. The corrected genetic/physical map of the region is presented in Fig. 2. The corrected positions of genes are presented in degrees relative to the origin of replication. We calculated the size of a DNA fragment corresponding to one degree on the chromosome by dividing the determined genome size (4214807 bp; Kunst *et al.*, 1997) by 360. According to this calculation, one degree on the chromosome corresponds to 11708 bp.

Assignment of ORFs

ORFs were sought in all six possible reading frames and selected according to the following criteria. A putative ORF should have an ATG, TTG or GTG start codon preceded within 5–15 bp by a Shine–Dalgarno (SD) sequence that is (partly) complementary to the 3' end of the *B. subtilis* 16S rRNA (3'-UCUUUCCUCCACUAG-5'). We also selected ORFs on the basis of codon usage

Fig. 2. Update of the genetic map of the *prkA*-*addAB* region. (a) Part of the genetic map of the *B. subtilis* chromosome according to Anagnostopoulos *et al.* (1993). Numbers above the line representing the map indicate the position, in degrees, relative to the origin of replication. (b) Corrected map of the region based on sequence data. Numbers above the line indicate positions in degrees relative to the origin of replication, as deduced from the total genome sequence, with one degree calculated to be 11708 bp.

statistics, using the Bsu.cod table on the EMBL CD-ROM. In total, 170 ORFs were identified, and these are indicated in Fig. 1. The protein coding density of this region is 90%. Fifty-eight per cent of the putative ORFs are transcribed in the direction of replication fork movement (clockwise); forty-two per cent are transcribed in the counterclockwise direction. The classification of these ORFs according to their putative function (also indicated in Fig. 1) is described in the following section.

Table 2 lists the coordinates of the ORFs relative to the first base in this region, the sizes of the deduced products in amino acids, the calculated molecular masses (kDa) and pIs, and the putative SD sequences. The nomenclature of the ORFs is according to agreements made among the participants in the European/Japanese *B. subtilis* genome sequencing project.

Deduced gene products and similarity analysis

All deduced amino acid sequences from putative genes within this region were compared to known protein sequences in public databases, and to the putative protein products encoded by the *B. subtilis* chromosome.

The similarity of deduced protein products from the sequenced region with known protein sequences in the databases is presented in Table 3. On the basis of similarity to known proteins, we propose that *yhxB* corresponds to the *gtaC* marker and *yhaF* corresponds to the *glyB* marker (see also below).

We classified all ORFs according to their putative function (the results of which are summarized in Fig. 1).

The different global classes of functions are mainly as described by Kunst *et al.* (1997). 'Cell envelope and cellular processes' includes proteins involved in cell wall metabolism, transport/binding proteins, lipoproteins, and proteins involved in membrane bioenergetics, mobility, chemotaxis and sporulation. 'Intermediary metabolism' includes proteins involved in the metabolism of carbohydrates, amino acids, nucleotides and nucleic acids, and coenzymes and prosthetic groups. 'Information pathways' includes proteins involved in DNA synthesis, restriction/modification, recombination and repair, RNA synthesis, and protein synthesis. 'Other' includes functions like antibiotic production, drug (-analogue) sensitivity, and adaptation to atypical conditions ('stress proteins').

The availability of the entire *B. subtilis* genome sequence (Kunst *et al.*, 1997), enabled us to search for paralogues on the *B. subtilis* chromosome. For this purpose, paralogues were defined as proteins, encoded by the *B. subtilis* chromosome, showing a minimum of 25% identity over at least three-quarters of their amino acid sequence. The numbers of paralogues for the ORF products in the region analysed here are listed in the second column of Table 3. The frequency distribution of paralogous sequences from the region studied here is summarized in Fig. 3. A considerable number of genes in this region have one or more paralogues: only 38% of the deduced proteins are unique, about 23% have one paralogue, 12% have two paralogues, etc. Some protein families have very many representatives. For instance, more than 60 members of the ABC transporter family are present on the *B. subtilis* chromosome, with six

terminator-like sequences are indicated. The ORFs were classified as follows: , genes of unknown function without homologues in public databases; , genes of unknown function with unknown homologues in public databases; , genes involved in information pathways; , genes involved in intermediary metabolism; , genes for cell envelope and cellular processes; , other. ϕ , Terminator-like sequence. See text for further details.

Table 2. Coordinates of ORFs within the *prkA-addAB* region, the size of their deduced products in amino acids and kDa, the calculated pI, and the putative SD sequence and initiation codon

In the column 'ORF', bold letters represent genes which have already been characterized in other studies. In the column 'endpoints', a right-pointing arrow means that the ORF is transcribed clockwise on the chromosome; left-pointing arrows indicate putative genes that are transcribed counterclockwise. In the column 'SD consensus sequence and initiation codon', bases that are complementary to the 16S rRNA are indicated with capitals; the putative initiation codon is indicated in bold capitals. NP, Not present. When an alternative possible initiation codon was found, it is also indicated in bold.

representatives in this region: *yhaD*, *yhaQ*, *yhcG*, *yhcH*, *yheI* and *yheH*. The paralogue frequency distribution observed within this region is globally similar to what is observed for the entire genome (Kunst *et al.*, 1997).

Identification of the *glyB* gene

The homology of the deduced amino acid sequence of ORF *yhaF* to several phosphoserine aminotransferases, or SerC proteins, from other organisms (see Table 3) suggested that *yhaF* might correspond to the *glyB* marker. The SerC protein is involved in the biosynthesis of serine: it catalyses the conversion of 3-phosphohydroxypyruvate to 3-phosphoserine, which is subsequently converted to serine by phosphoserine phosphatase (SerB). Glycine is metabolically derived either from serine by serine hydroxymethyltransferase (GlyA), or from threonine by threonine aldolase (Stauffer, 1983). To confirm that *yhaF* indeed corresponded to the *glyB* marker, we transformed *B. subtilis* strain 1A5 (*glyB133 metC3 tre-12 trpC2*; Dedonder *et al.*, 1977) with a *B. subtilis* plasmid carrying the entire *yhaF* coding sequence under control of a constitutive promoter. This plasmid, and not its parental plasmid without ORF *yhaF*, did complement strain *B. subtilis* 1A5 with respect to glycine auxotrophy when cultured in minimal medium. This indicates that *yhaF* corresponds to the *glyB* marker.

Evidence for non-functional (remnants of) genes

In the region studied, several ORFs were found of which the deduced proteins are almost certainly not functional

or not expressed. This is likely to be due to rearrangements and/or deletions within the coding sequence or absence of proper transcriptional or translational signals for expression. Based on repeated sequence analysis of these regions, we feel confident that these findings are not the result of sequencing errors. The first example is the *yzdE*-*yzdF* pair of partially overlapping ORFs, which code for the N-terminal (*yzdE*) and C-terminal (*yzdF*) fragments, respectively, of a protein that is present in its entirety in *E. coli* (EmrA; Lomovskaya & Lewis, 1992) and *H. influenzae* (EmrA; Fleischmann *et al.*, 1995). When compared to the *E. coli* and *H. influenzae* genes, the middle 350 bp are absent in *B. subtilis*, which also results in a frameshift (Fig. 4). Moreover, *yzdE* is preceded by proper translational start signals (a SD sequence followed by an ATG start codon), but such signals are absent upstream of *yzdF*.

The second example is *yhaV*. Its deduced ORF product displays significant homology to several HemN proteins, or anaerobic coproporphyrinogen III oxidases involved in haem synthesis under anaerobic conditions, from *H. influenzae* (383 aa), *E. coli* (457 aa), *Salmonella typhimurium* (457 aa) and *Rhodobacter sphaeroides* (305 aa). However, no possible translational start site could be found for *yhaV*, and the homology is mainly restricted to the N-terminal two-thirds of the protein.

Another interesting ORF is located upstream of, and partially overlapping with, *yhaE*. ORF *yhaE* encodes a possible *B. subtilis* representative of the ubiquitous Hit-like protein (Seraphin, 1992). The first member of this family of proteins was isolated from bovine tissue and

Table 3. Deduced ORF products, the number of paralogous sequences, and their similarities with protein sequences in public databases

Proteins that were previously known are indicated in bold. In the second column, the numbers of paralogous sequences within the *B. subtilis* genome are indicated. Hypo, hypothetical protein (no experimental evidence for its function). SP, Swiss Prot; GB, GenBank; E, EMBL; GP, GenPept. The final column gives the percentage identity, the Smith–Waterman score (S–W score), and the length of the homology, in amino acids.

YhcW	3	Phosphoglycolate phosphatase from <i>Alcaligenes eutrophus</i>	SP: P40852	25, 179, 186
		A family of hypothetical proteins (like YieH from <i>E. coli</i>)	SP: P31467	27, 204, 181
YhcX	0	Nitrilase 2 from <i>Arabidopsis thaliana</i>	SP: P32962	34, 156, 103
		A hypothetical protein from <i>S. cerevisiae</i>	PIR: S51459	27, 326, 292
YhxA	6	DAPA aminotransferase (BioA) from <i>Bacillus sphaericus</i>	SP: P22805	34, 839, 446
GlpP	1	= Glycerol operon regulator GlpP from <i>B. subtilis</i>	SP: P30300	100
GlpF	2	= Glycerol uptake facilitator GlpF from <i>B. subtilis</i>	SP: P18156	100
GlpK	2	= Glycerol kinase GlpK from <i>B. subtilis</i>	SP: P18157	100
GlpD	0	= Glycerol-3-phosphate dehydrogenase GlpD from <i>B. subtilis</i>	SP: P18158	100
YhxB	1	Phosphomannomutase or phosphoglucomutase from <i>Mycoplasma pirum</i>	PIR: E53312	28, 793, 564
YhcY	0	Sensory transduction kinase DegS from <i>B. subtilis</i>	SP: P13799	31, 261, 221
YhcZ	15	Transcriptional regulator DegU from <i>B. subtilis</i>	SP: P13800	39, 517, 219
YhdA	2	Hypo YieF from <i>E. coli</i>	SP: P31465	26, 174, 136
YhdB	0	None		
YhdC	0	None		
YhdD	2	Phosphatase-associated protein PapQ from <i>B. subtilis</i>	GB: U38819	50, 943, 316
YhdE	1	Hypo YjeB from <i>E. coli</i>	SP: P40610	44, 393, 142
YgxB	0	= YgxB from <i>B. subtilis</i> (partial)	SP: P37874	100
		Hypo from <i>Synechococcus</i> sp.	PIR: S20924	28, 248, 173
SpoVR	0	= Stage V sporulation protein SpoVR from <i>B. subtilis</i>	SP: P37875	100
PhoAIV	1	= Alkaline phosphatase PhoAIV from <i>B. subtilis</i>	SP: P19406	100
PapQ	4	= Phosphatase-associated protein PapQ from <i>B. subtilis</i>	E: U38819	100
CitR	2	= Negative regulator for <i>citA</i> , <i>CitR</i> , from <i>B. subtilis</i>	SP: P39127	100
CitA	2	= Citrate synthase I <i>CitA</i> from <i>B. subtilis</i>	SP: P39119	100
YhdF	21	Glucose and ribitol dehydrogenase from <i>Hordeum vulgare</i> (barley)	GP: S7226	52, 952, 286
YhdG	5	Hypo from <i>Mycobacterium tuberculosis</i>	Z79702/g264157	41, 1269, 464
		Cationic amino acid transporter from <i>Homo sapiens</i>	D29990/g849051	36, 893, 435
YhdH	1	Hypo YG90 from <i>Haemophilus influenzae</i>	SP: P455320	36, 1064, 457
YhdI	5	Probable rhizopine catabolism regulatory protein MocR from <i>Rhizobium meliloti</i>	SP: P49309	34, 897, 481
		Aminotransferase from <i>Sulfolobus solfataricus</i>	E283830/g1707790	27, 397, 370
YhdJ	0	Regulator of alkylphosphate uptake PhnO from <i>E. coli</i>	SP: P16691	34, 136, 82
YhdK	4	None		
YhdL	0	None		
YhdM	7	Putative RNA polymerase sigma factor YbbL from <i>B. subtilis</i>	D84214/g1256141	31, 280, 160
YhdN	5	Hypo YxbF from <i>B. subtilis</i>	SP: P46336	37, 704, 311
		Potassium channel $\beta 2$ subunit from <i>Homo sapiens</i> (human)	U33429/g995761	30, 402, 334
YhdO	0	Hypo from <i>Synechocystis</i> sp.	D90915/g1653690	26, 200, 180
YhdP	4	YhdT from <i>B. subtilis</i>	This paper	61, 1687, 430
		Haemolysin from <i>Synechocystis</i> sp.	D90914/g1653594	30, 677, 441
YhdQ	2	Hypo HI1623 from <i>H. influenzae</i>	SP: P45277	33, 184, 120
		Mercury resistance regulatory protein MerR from <i>Thiobacillus ferrooxidans</i>	SP: P22896	35, 154, 87
YhdR	4	Aspartate aminotransferase from <i>Methanococcus jannaschii</i>	U67459/g1592252	30, 520, 391
YhdS	0	Hypo from fowlpox virus (small internal fragment)	SP: P21973	44, 63, 25
YhdT	4	YhdP from <i>B. subtilis</i>	This paper	61, 1687, 430
		Haemolysin from <i>Synechocystis</i> sp.	D90914/g1653594	31, 683, 439

Table 3. (cont.)

ORF product	No. of paralogues	Similar protein(s) in databases	Database accession no.	% Identity, S-W score, overlap (aa)
YhdU	2	NADH-plastoquinone oxidoreductase chain 2 (chloroplast) from <i>Marchantia polymorpha</i>	SP: P06257	24, 125, 122
YhdV	5	None		
YhdW	2	Glycerol diester phosphodiesterase GlpQ from <i>B. subtilis</i>	SP: P37965	38, 575, 252
YhdX	0	Hypo human transposon L1.1 ORF1	M80340/g339770	32, 60, 34
YhdY	0	Hypo MJ1143 from <i>M. jannaschii</i>	g1591775	27, 550, 357
YhdZ	0	Lac repressor LacR from <i>S. aureus</i>	M32103/g845686	36, 446, 251
YheN	1	Hypo Yfu2 from <i>B. stearotheophilus</i>	SP: Q04729	32, 305, 205
YheM	2	D-Amino acid aminotransferase from <i>B. licheniformis</i>	U26947/g857561	64, 1179, 275
YheL	1	Na ⁺ /H ⁺ antiporter from <i>B. firmus</i>	SP: P27611	53, 1377, 390
YheK	1	Hypo YxiE from <i>B. subtilis</i>	SP: P42297	30, 230, 166
YheJ	0	None		
YheI	11	Multidrug-resistance-like ATP binding protein MDL from <i>E. coli</i>	SP: P30751	37, 1134, 507
YheH	9	Multidrug-resistance-like ATP binding protein MDL from <i>E. coli</i>	SP: P30751	40, 1341, 519
YheG	2	Flavin reductase FLR from <i>Bos taurus</i> (bovine)	SP: P52556	27, 211, 208
YheF	0	None

Fig. 3. Parologue frequency distribution of ORFs in the *prkA-addAB* region compared to all *B. subtilis* protein sequences. On the x-axis, the number of paralogues for a given protein sequence is indicated, and on the y-axis the number of proteins encoded within the *prkA-addAB* region for which this number of paralogues is found.

identified as being a protein kinase C inhibitor (Pearson *et al.*, 1990). The ORF in front of *yhaE* (results not shown) is 120 codons long, and its deduced amino acid sequence displays blocks of similarity with the catalytic subunit of human DNA-dependent protein kinase (database reference PIR: A57099). However, the latter protein is 4096 aa long. This may be due to 'background noise', but the coincidence of finding these blocks of similarity to a protein kinase together with a gene encoding a putative protein kinase C inhibitor is striking.

A similar situation was found downstream of *yhaG*. The deduced YhaG product displays similarity to ProW from *E. coli*, which is involved in a multicomponent binding-protein-dependent transport system for glycine betaine/L-proline (Gowrishankar, 1989). Downstream of *yhaG*, a small ORF was found that shows some similarity to glycine receptor beta subunits from mouse (database reference GP: MMGRBMRA_1), rat (SP: GRB_RAT) and human (SP: GRB_HUMAN) and an unknown ORF product from *Arabidopsis thaliana*. The deduced ORF product is only 63 aa long, while the

Fig. 4. Homology comparison of EmrA amino acid sequences (multidrug resistance protein A) from *H. influenzae* and *E. coli*, and the deduced protein products of *yzdE* and *yzdF*. Amino acid residues that are conserved between *E. coli* and *H. influenzae* are indicated in bold; amino acid residues that are identical in all three organisms are indicated with an asterisk below the three sequences; amino acid residues that are conserved are indicated with a dot.

glycine receptor beta subunits are 484, 496 and 497 aa long, respectively, and the similarity is restricted to three small blocks of amino acids. However, a proper SD sequence with accompanying start codon is present in front of this ORF (AAAGGAGGgagaaggTTG). Functional analysis will hopefully reveal the biological relevance of the above-mentioned features.
